# Autophagy

Autophagy is a way that cells use for organelles recycling<sup>1</sup>. The main process involves the segregation and delivery of cytoplasmic cargo, including proteins and organelles, for degradation by hydrolytic enzymes in lytic vacuoles (lysosomes) also called "autophagolysosomes" or "autolysosomes". Three types of autophagy have been described in the literature so far<sup>2</sup>:

- macroautophagy that sequesters damaged organelles and unused proteins,
- microautophagy in which lysosomes directly engulf cytoplasm by invagination of the membrane,
- chaperone-mediated autophagy that selectively sequesters proteins containing a consensus sequence recognised by the Hsc70-containing chaperone/co-chaperone complex.

Although described in the early 60's, it is only recently that autophagy has gained interest for its implication as a basal mechanism in cell homeostasis and development. A number of studies are also aimed to determine the role of induced autophagy in host-pathogen interaction<sup>3</sup>, cell survival under stress conditions and diseases (neurodegenerative diseases and cancer).

Covalab provides antibodies targeting key components of the autophagic pathway, like Beclin-1 and Atg proteins implicated in autophagosomes formation, caspases involved in autophagic programmed cell death or lytic enzymes and membrane proteins playing a role in vacuole function. Discover these antibodies and more products in the following list.
